Install outside the devbox	6

Setup

To use the **cicd** command, you need to fill in the [configuration file](#) located in `/vagrant/config/shell`.

The cicd shell is installed with the devbox. Please read the section *Install_outside_the_devbox* if you need to install it on a different system.

Usage

The name of the command line utility is **cicd**. The first mandatory position argument is the zone (dev, testing, staging or prod). The general scheme of the command line is:

```
cicd ZONE facts          [ROLE] [-n NODE] [-g GROUP] [-s STACK] [-a --all] [-d --down]
cicd ZONE runpuppet      [ROLE] [-n NODE] [-g GROUP] [-s STACK]
cicd ZONE runpuppet      [ROLE] [-n NODE] [-g GROUP] [-s STACK]
cicd ZONE ping           [ROLE] [-n NODE] [-g GROUP] [-s STACK]
cicd ZONE data [-k KEY] [ROLE] [-n NODE] [-g GROUP] [-s STACK]
cicd ZONE orch           CMD                                [-s STACK]
cicd ZONE service        ACTION SERVICE [ROLE] [-n NODE] [-g GROUP] [-s STACK]
cicd ZONE console
```

Here is the help as display by invoking **cicd** alone:

→ `cicd`

CICD command line utility (v1.1.1)

Usage: `cicd ZONE (console | stats | data | orch | facts | ping | du | service
runpuppet | sync | result | gentags)`

Available options:

<code>-h, --help</code>	Show this help text
<code>ZONE</code>	ZONE such as dev, staging, testing or prod

Available commands:

<code>console</code>	Open the specialized salt console
<code>stats</code>	Stats (special permission required)
<code>data</code>	Return configuration data for a specific property
<code>orch</code>	Run an orchestration command on the infrastructure
<code>facts</code>	Return essential facts about nodes
<code>ping</code>	Ping nodes
<code>du</code>	Return disk usage
<code>service</code>	Service management for a specific node
<code>runpuppet</code>	Apply puppet configuration
<code>sync</code>	Sync data from master to nodes
<code>result</code>	Display the results of jobs executed by the user
<code>gentags</code>	Generate node completion file

You can request the help at each level. For instance:

→ `cicd staging facts -h`

- Commands are executed remotely through an API. Behind the scene they call either the `puppetdb`, the `saltmaster` or the `pgserver`.
- Commands to the saltmaster together with their results are recorded in a centralized database included the date and name of the person that executes them.
- By default, all commands target a specific default hostgroup/stack defined in `/vagrant/conf/shell`

>_ facts

The command displays a subset of important facts (static information) about your nodes such as the `fqdn`, `ip`, `os`, `role`, ...

You can toggle the `facts` query to target all hostgroups/stacks with the `-a/ --all` flag. Here is how to get all facts for all slaves in every stack:

```
λ ~ → cird prod facts jenkins.slave --all
{
  "fqdn": "SVAPPCAVL595.cirb.lan",
  "ip": "192.168.34.153",
  "os": "CentOS 6.6",
  "hostgroup": "irisbox",
  "subgroup": "jenkins",
  "role": "slave"
  "puppet run": "Tue Apr 18 14:26:15 CEST 2017",
  "jenkins job": "633"
}
{
  "fqdn": "SVAPPCAVL649.prd.srv.cirb.lan",
  "ip": "192.168.34.9",
  "os": "RedHat 6.7",
  "hostgroup": "iam",
  "subgroup": "jenkins",
  "role": "slave"
  "puppet run": "Tue Apr 18 14:26:15 CEST 2017",
  "jenkins job": "633"
}
...
```

As usual, use **-n** to target a single node:

```
→ cird prod facts -n svappcavl771.prd.srv.cirb.lan
{
  "fqdn": "svappcavl771.prd.srv.cirb.lan",
  "ip": "192.168.34.81",
  "os": "RedHat 7.2",
  "hostgroup": "fmx",
  "subgroup": "jenkins",
  "role": "slave",
  "puppet run": "Thu Jan 26 11:06:00 CET 2017",
  "jenkins job": "30"
}
```

Use the **--down** flag to gather **facts** on a disconnected minion.

>_ data

The command displays configuration data about your node. For instance you might display the docker version of your jenkins slave:

```
→ cird prod data jenkins.slave -k docker::version
{
  "fqdn": "svappcavl736.cirb.lan",
  "subgroup": "jenkins",
  "role": "slave",
  "docker::version": "1.9.1-25.e17"
}
```

To display ALL known configurations for a specific node:

```
→ cird prod data -n svappcavl771.prd.srv.cirb.lan
```

>_ **runpuppet**

The command runs the puppet agent on one or multiple nodes. When a node is specified with **-n**, the command will wait back for a result.

```
→ cird dev runpuppet -n svappcavl000.dev.srv.cirb.lan
```

On all other cases, the command first asks for confirmation, then returns quickly with a **jobid**. The process is asynchronous because it might take quite a while to complete.

Here are some examples:

```
→ cird dev runpuppet ①
→ cird dev runpuppet -g jenkins ②
→ cird dev runpuppet jenkins.slave ③
```

① run puppet on all the dev nodes of your stack

② run on a subgroup of machines

③ target a role

In a second step, you use >_ **result** to retrieve from the database the result of your call [1: polling is currently the sole supported workflow, server push notification could be implemented in the future].

>_ **result**

You can view the result of a **runpuppet** by using the provided job id (**jid**)

```
→ cird testing result -j 20160621104434055991
```

In case the result is not yet available the command will automatically be retry 12 times (3 min).

You can also ask for the last n executed commands:

```
→ cicc testing result -n 2
```

>_ service

To know if a service is up and running, you would use:

```
→ cicc prod service status docker jenkins.slave
{
  "svapccavl736.prd.srv.cirb.lan": true
}
```

You can also restart a service. However such operation is only allowed for a single machine. Here is how to restart the **nexus** service :

```
→ cicc prod service restart nexus -n svapccavl761.prd.srv.cirb.lan
{
  "svapccavl761.prd.srv.cirb.lan": true
}
```

>_ du

The command displays disk usage. Try:

```
→ cicc staging du -n svapccavl703.sta.srv.cirb.lan
```

>_ console

For longer session within a specific zone, you can save some typing by opening a **console** for that zone. Inside the console, you would omit the zone from the command line. Here is an example:

```
→ cicc staging console
```

```
[cicc prod]$ facts
```

Another usage of the console is to run specific **salt** commands that are not exposed by the **cicc** command line. This is done via the pep shortcut. For instance:

```
$ pep -G 'hostgroup:iam' file.replace '/etc/resolv.conf' pattern='192.168.34.250' repl='192.168.34.244' ①
$ pep -L fqdn1,fqdn2 --client=local_async puppetutils.run_agent ②
```

① -G means **grain** target (*grains* is the salt terminology for facts).

② -L means **list** target

local_asyn means the :autofit-option:command is asynchronous and does not display its result (just a jid)

- Have a look at the saltstack documentation to learn more about [targeting minions](#).
- Take a look [here](#) for a list of possible commands.

>_ orch

Salt can run multiple commands as well using the orchestrate runner. The orchestration is executed on the salt master to allow inter minion requisites, like ordering the application of states on different minions that must not happen simultaneously, or for halting the state run on all minions if a minion fails one of its states (more about this topic can be found [in the saltstack website](#)).

The orchestration should be defined in the orch folder. You will find some examples [here](#).

Orchestrate commands can be started using:

```
→ cicc testing orch CMD
```

Authentication

The permissions to target machines and perform actions are realized through our Active directory. As an example to access the machines of the **middleware** hostgroup, you will need to be part of the **GP_APP_SALT_MIDDLEWARE** group.

These permissions should have been set for you already. If they don't, please contact the **cicc** team.

Install outside the devbox

Before installing the **cicc-shell** on any linux system [2: **macos** might also work], you will need:

1. the [nix package manager](#) installed and active for your user.
2. the [cicrb nixpkgs config](#)

You can then proceed to install with:

```
nix-env -f ~/.config/nixpkgs/pin.nix -i cicc-shell ①
```

① the `-f` flag ensures that we point to the same nixpkgs version but can be omitted

If you haven't installed `nix` already, here is the quick how to:

```
bash <(curl https://nixos.org/nix/install)
```

This will perform a single-user installation of Nix, meaning that `/nix` is owned by the invoking user. The script will only invoke `sudo` to create `/nix` if it doesn't already exist. At that point, the script will prompt you for a password.

To activate `nix` in your shell, add the following line in your `.bash_profile`:

```
source ~/.nix-profile/etc/profile.d/nix.sh'
```
